

ABSTRACT

A system for value-mapping includes software and a graphical user interface including a value mapping table to allow comparisons of mapped values in the graphical user interface. The value mapping table may include at least two columns and at least one row, in which at least one column represents a domain and at least one row includes a value, which may represent an object or data. A first value in a first domain can be mapped to a second value in a second domain. The first and second values can be in the same row of the value mapping table. The first value in the first domain may have a different representation of an object from the second value in the second domain. The first and second values may relate to the same object.
